

Answer 1)

Formula utilized : $\text{Time} = (\text{Number of Instructions} * \text{CPI}) / \text{Clock rate}$

As per the question, O is optimized and UO is unoptimized.

Given -

$$\text{Clock rate}_O = 0.95 * \text{Clock rate}_{UO}$$

$$\text{NOI}_{UO} = 0.30 \text{ (Load and store)} + 0.7 \text{ (Others instructions)}$$

$$\text{NOI}_O = \frac{2}{3} * \text{NOI}_{UO} \text{ (Number of instructions of load and store)}$$

$$\text{CPI} = 1$$

$$\text{Time}_O = (\text{NOI}_O) * \text{CPI} / \text{Clock rate}_O$$

$$= (\frac{2}{3} * 0.3) + (0.7) \text{NOI}_{OU} * 1 / 0.95 * \text{Clock rate}_{UO}$$

$$= 0.9 \text{NOI}_{OU} / 0.95 * \text{Clock rate}_{UO}$$

$$\text{Time}_{OU} = (\text{NOI}_{OU}) * \text{CPI} / \text{Clock rate}_{OU}$$

$$= \text{NOI}_{OU} * 1 / \text{Clock rate}_{UO}$$

$$\text{Speedup} = \text{Time}_{OU} / \text{Time}_O$$

$$= (\text{NOI}_{OU} * 1 / \text{Clock rate}_{UO}) / (\frac{2}{3} * \text{NOI}_{OU} * 1 / 0.95 * \text{Clock rate}_{UO})$$

$$= 0.95 / 0.9$$

$$= 1.06$$

The optimized system is faster by 6% than unoptimized version while optimizing the 6%.

Answer 2)

a)

Formula utilized: $\text{Speedup of B wrt A} = \text{throughput}_A / \text{throughput}_B$

Using table 2,

$$\begin{aligned} \text{Speedup of TPU with GPU A} &= \text{throughput of TPU A} / \text{throughput of GPU A} \\ &= 2,25,000 / 13,461 = 16.715 \end{aligned}$$

$$\begin{aligned} \text{Speedup of TPU with GPU B} &= \text{throughput of TPU B} / \text{throughput of GPU B} \\ &= 2,80,000 / 36,465 = 7.678 \end{aligned}$$

$$\text{Total time of TPU over GPU} = 0.3 T (A) + 0.7 T (B)$$

As per the given information,

$$16.715 * \text{Time}_{\text{taken_TPU_A}} = 0.7 * T \text{ (Time taken by GPU of A)}$$

$$7.678 * \text{Time}_{\text{taken_TPU_B}} = 0.3 * T \text{ (Time taken by GPU of B)}$$

$$\text{Speedup of TPU wrt GPU} = \text{Time}_{\text{taken_GPU}} / \text{Time}_{\text{taken_TPU}}$$

$$= T / (0.7/16.715 + 0.3/7.678) T$$

$$= 1 / (0.0418 + 0.039)$$

$$= \mathbf{12.37 \text{ times}}$$

b)

Formula utilized : $\text{Performance} = \text{clock rate}/\text{CPI (Cycles per instruction)}$
 $= \text{Max IPS of A} * \text{time} + \text{Max IPS of B} * \text{time}$

Time spent on A = 0.70

Time spent on B = 0.30

- I. General Purpose Performance = $0.42 * 0.70 + 1.00 * 0.3 = \mathbf{0.594 \text{ or } 59.4\%}$
- II. Graphics Processor Performance (GPU) = $0.37 * 0.70 + 1.00 * 0.3 = \mathbf{0.559 \text{ or } 55.9\%}$
- III. TPU Performance = $0.80 * 0.70 + 1.00 * 0.3 = \mathbf{0.86 \text{ or } 86\%}$

c)

Formula utilized:

$\text{Power consumed} = \text{IDLE Power} + (\text{Busy Power} - \text{IDLE Power}) * \text{Max IPS of system}$

$\text{Performance per watt} = \text{Power consumed} * \text{number of instructions with max IPS (n)}$

$$\begin{aligned}\text{PC_GPU} &= 357 + [(991 - 357) * 0.559] \\ &= 711.406 \text{ W}\end{aligned}$$

$$\begin{aligned}\text{PC_TPU} &= 290 + [(384 - 290) * 0.86] \\ &= 370.84 \text{ W}\end{aligned}$$

$$\begin{aligned}\text{Performance per watt of TPU system over GPU system} &= ((0.86 * n) / 370.84) / ((0.559 * n) / 711.406) \\ &= \mathbf{2.95}\end{aligned}$$

d)

Formula utilized : $\text{Speedup of B wrt A} = \text{throughput_A} / \text{throughput_B}$

$$\begin{aligned}\text{Speedup of general processor (GP) over TPU} &= 0.4 / (\text{Speedup of TPU/GP of A}) + 0.1 / (\text{Speedup of TPU/GP of B}) + 0.5 / (\text{Speedup of TPU/GP of C}) \\ &= 0.4 / (\text{Throughput of TPU/GP of A}) + 0.1 / (\text{Throughput of TPU/GP of B}) + 0.5 / (\text{Throughput of TPU/GP of C}) \\ &= 0.4 / (225000/5482) + 0.1 / (280000/13194) + 0.5 / (2000/12000) \\ &= 0.4 / 41.043 + 0.1 / 21.22 + 0.5 / 0.167 \\ &= 3.0084\end{aligned}$$

Speedup of TPU over GP becomes $1 / 3.0084$ i.e., 0.332 times

Similarly,

Speedup of GPU over GP becomes $1 / X$ i.e., 1.789 times

$$X = 0.4 / (\text{Speedup of GPU/GP of A}) + 0.1 / (\text{Speedup of GPU /GP of B}) + 0.5 / (\text{Speedup of GPU /GP of C})$$

$$\begin{aligned}
&= 0.4 / (\text{Throughput of GPU /GP of A}) + 0.1 / (\text{Throughput of GPU /GP of B}) + 0.5 / (\text{Throughput of GPU /GP of C}) \\
&= 0.4 / (13461/5482) + 0.1 / (36,465/13194) / + 0.5 / (15,000/12000) \\
&= 0.4 / 2.45 + 0.1 / 2.76 + 0.5 / 1.25 \\
&= 0.599
\end{aligned}$$

e)

Cooling door = 14000W

GP = $14 \times 10^3 \text{ W} / \text{TDP (504W)}$ \approx **28 servers** that can be cooled from 1 cooling door.

GPU = $14 \times 10^3 \text{ W} / \text{TDP (1838W)}$ \approx **8 servers** that can be cooled from 1 cooling door.

TPU = $14 \times 10^3 \text{ W} / \text{TDP (861W)}$ \approx **16 servers** that can be cooled from 1 cooling door.

GP from Haswell having ~ 28 servers can be cooled from 1 cooling door.

f)

Server Rack = 11 sq feet

Max dissipation = 200 W per sq feet

$$\begin{aligned}
\text{Maximum power per server rack} &= \text{max power} * \text{length} \\
&= 200 \text{ W} / (\text{feet})^2 * 11 (\text{feet})^2 = 2200 \text{ W}
\end{aligned}$$

Therefore,

Max. # of GP Servers = $2200 \text{ W} / 504 \text{ W} = \sim 4$ **servers**

Max. # of GPU Servers = $2200 \text{ W} / 1838 \text{ W} = \sim 1$ **servers**

Max. # of GP Servers = $2200 \text{ W} / 861 \text{ W} = \sim 2$ **servers**

One cooling door (14kW) is enough to dissipate 2200W of energy.

Hence, with a single cooling door following number of racks are required -

GP = $14 \text{ kW} / (504 * 4) = \sim 7$ **GP server racks**

GPU = $14 \text{ kW} / (1838 * 1) = \sim 8$ **GPU server racks**

TPU = $14 \text{ kW} / (861 * 2) = \sim 8$ **TPU server racks**

Answer 3)

a)

Using Amdahl's law -

Formula utilized: Net Speedup = $1 / (1 - \text{PE}) + (\text{PE} / \text{faster times})$

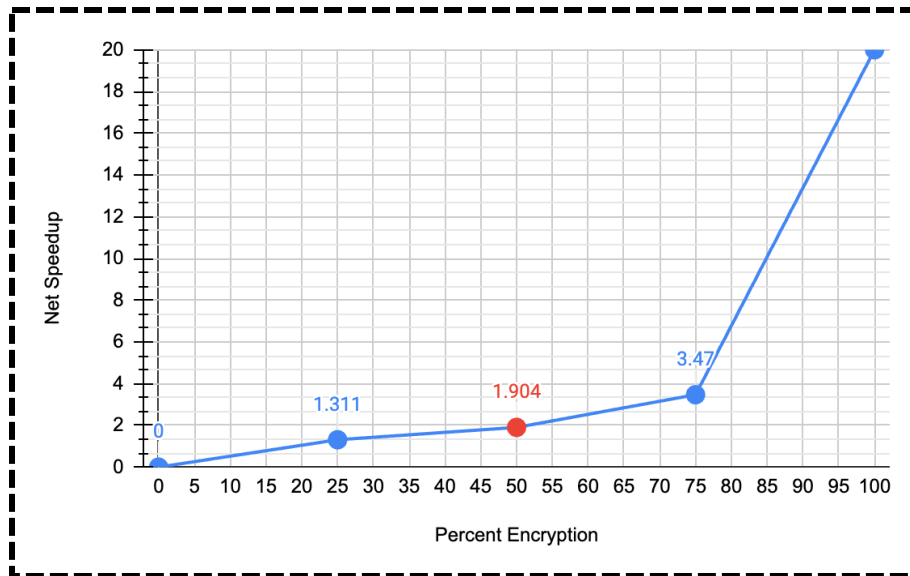

Computations for plotting the graph as Net Speedup being 1 initially =

Speedup of 25% encryption = $1 / (0.75 + 0.25/20) = 1.311$

Speedup of 50% encryption = $1 / (0.5 + 0.5/20) = 1.904$

Speedup of 75% encryption = $1 / (0.25 + 0.75/20) = 3.47$

Speedup of 100% encryption = $1 / (1/20) = 20$

b)

Formula utilized: $\text{Net Speedup} = 1 / (1 - \text{PE}) + (\text{PE} / \text{faster times})$

$$2 = 1 / (1 - x) + (x/20)$$

$x = 10/19 = 52.6\%$ encryption required for Speedup of 2.

c)

Formula utilized: $\text{Computation run time} = \text{encrypted} / \text{total time taken}$

From above, the value ($x = \text{speedup} = 2$) on Y corresponds to 52.6%

Original time taken for non-encrypted machine = $(100 - 52.6) * t / 100 = 0.474 t$

When the speedup is achieved, the total time becomes $t/2$. Hence, the time taken for encrypted machine will be = $(t/2) - 0.474 t = 0.5t - 0.474t = 0.026t$

Therefore, computation run time = encrypted / total time taken

$$= 0.026t / 0.5 t$$

$$= 0.26 / 5$$

$$= 0.052$$

I.e., 5.2% of computation run time is spent in encryption mode if 2% speedup is achieved.

Answer 4)

a)

Formula utilized: $\text{Speedup} = 1 / (1 - \text{time}) + (\text{time} / \text{faster times})$ [According to Amdahl's law]

Assumption –

Faster times of new = 10 = 1/ faster times of old

Time original (old) is 1 and Time enhanced (new) becomes 0.5

$$\text{Speed_new} / \text{Speed_old} = 1 / [(1 - \text{time_new}) + (\text{time_new} / \text{faster_times_new})]$$

- Equation 1

$$\text{Speed_old} / \text{Speed_new} = 1 / [(1 - \text{time_old}) + (\text{time_old} / \text{faster_times_old})]$$

$$\begin{aligned}
&= 1 / [(1 - 0.5) + (0.5 * 10)] \\
&= 1 / [(0.5) + (0.5 * 10)] \\
&= 1/5.5
\end{aligned}$$

Therefore,

Speed_new/Speed_old = **5.5 is the speedup obtained from fast mode**

- Equation 2

b)

Equating both the above equations –

$$5.5 = 1 / [(1 - \text{time_new}) + (\text{time_new} / 10)]$$

$$(1 - \text{time_new}) + (\text{time_new} / 10) = 1 / 5.5$$

$$1 - \text{time_new} + 0.1 \text{time_new} = 1 / 5.5$$

$$1 - 0.9 \text{time_new} = 0.1818$$

$$0.9 \text{time_new} = 0.818$$

time_new = 0.909 i.e., 90.9% time of the original execution time has been converted to fast mode

Answer 5)

a)

The speed will increase by the 80% parallelizing.

Formula utilized: Net Speedup = $1 / (1 - \text{speed_new}) + (\text{speed_new} / \text{faster times})$ [Using Amdahl's law]

$$\begin{aligned}
\text{New Speedup with N processors} &= 1 / (1 - 0.8) + (0.8/x) \\
&= 1 / (0.2) + 0.8 x
\end{aligned}$$

b)

The number of processors = 8 units

Formula utilized: Net Speedup = $1 / [(1 - \text{speed_new}) + (\text{speed_new} / \text{faster times} * \text{no of processors}) + ((\text{delay} * \text{no of processors})/100)]$

$$= 1 / [(1 - 0.8) + (0.8 / 8 \text{ processors}) + ((0.5 * 8 \text{ times}) / 100)]$$

$$= 1 / (0.2) + (0.1) + (0.04)$$

$$= 1 / (0.34)$$

= 2.94 is the net speedup for 8 times adding each of the processors

c)

Formula utilized: $\text{Net Speedup} = 1 / [(1 - \text{speed_new}) + (\text{speed_new} / \text{faster times} * \text{no of processors}) + ((\text{delay} * \text{no of processors})/100)]$

The number of processors will be doubled = 1 -> 2 -> 4 -> 8 i.e., 3 times

OR

$$2^3 = 8$$

$$\begin{aligned} &= 1 / [(1 - 0.8) + (0.8 / 8 \text{ processors}) + ((0.5 * 3 \text{ times}) / 100)] \\ &= 1 / (0.2) + (0.1) + (0.0015) \\ &= 1 / (0.3015) \\ &= \mathbf{3.316 \text{ is the net speedup for 3 times doubling the processors}} \end{aligned}$$

d)

The number of processors will be doubled by the formula $2^x = N$ (given N is the number of processors).
The final equation becomes $x = \log_2 N$ (as per the above derived equations).

$$\mathbf{\text{Speedup} = 1 / [(1 - 0.8) + (0.8 / N \text{ processors}) + ((0.5 * \log_2 N \text{ times}) / 100)]}$$

e)

The original execution time (here PV) is P% hence, the equation becomes

$$\mathbf{\text{Speedup} = 1 / [(1 - P) + (P / N \text{ processors}) + ((0.5 * \log_2 N \text{ times}) / 100)]}$$

Further solving the term -

For speedup to be highest, the derivative of N should be 0 (derived from motion equation i.e., when ball tossed in air reaches the max height graph)

$$D(\text{Speedup}) / DN = [1 / ((1 - P) + (P / N \text{ processors}) + (0.005 * \log_2 N \text{ times}))]^{-2} * [(0.005 / N * \log_e 2) + (P / N^2)] * (-1) = 0$$

Equating the later term with 0, we get -

$N = 200 P \log_e 2$ as the final equation for getting the highest speedup depending on number of processors available.

Answer 6)

Percentage Parallelizable (PP)

Formula utilized: $\text{Net Speedup} = 1 / (1 - PP) + (PP / \text{optimization} / \text{parallel processors})$

a)

$$\text{Speedup} = \text{Speed_serial} / \text{Speed_parallel}$$

$$= 1 / [(1 - 0.5) + (0.5/22 \text{ cores})] = 1 / (0.5227) = \mathbf{1.913 \text{ i.e., 91\% speedup}}$$

b)

Similarly, as done in part a,

$$\text{Speedup} = \text{Speed_serial} / \text{Speed_parallel}$$

$$= 1 / ((1 - 0.9) + (0.9/22 \text{ cores})) = 1 / (0.1409) = 7.096 \text{ i.e., } \mathbf{610\% \text{ speedup}}$$

c)

41% cores (resources) are allocated to A i.e., $22 * 0.41 = \sim 9$ cores

Speedup of A

$$= 1 / ((1 - 0.5) + (0.5/9 \text{ cores}))$$

$$= 1.8 \text{ i.e., } \mathbf{80\% \text{ speedup in A}}$$

$$\text{Overall speedup} = 1 / (1 - 0.41) + (0.41/1.8)$$

$$= 1.22 \text{ i.e., } \mathbf{22\% \text{ overall speedup of A}}$$

d)

$$27\% \text{ cores for B} = 22 * 0.27 = \sim 6 \text{ cores}$$

$$18\% \text{ cores for C} = 22 * 0.18 = \sim 4 \text{ cores}$$

$$14\% \text{ cores for D} = 22 * 0.14 = \sim 3 \text{ cores}$$

Speedup of A (from c part) = **1.8 times**

$$\text{Speedup of B} = 1 / (1 - 0.8) + (0.8/6 \text{ cores}) = \mathbf{3 \text{ times}}$$

$$\text{Speedup of C} = 1 / (1 - 0.6) + (0.6/4 \text{ cores}) = \mathbf{1.818 \text{ times}}$$

$$\text{Speedup of D} = 1 / (1 - 0.9) + (0.9/3 \text{ cores}) = \mathbf{2.5 \text{ times}}$$

e)

$$\text{Speedup overall} = 1 / (0.41/1.8 + 0.27/3 + 0.18/1.818 + 0.14/2.5)$$

$$= 1 / (0.227 + 0.09 + 0.01 + 0.056)$$

$$= 1/0.383$$

= **2.61 % overall speedup** of the resources, considering only active time on their statically assigned cores

Answer 7)

Formula utilized: $\text{Net Speedup} = 1 / (1 - \text{time_taken_new}) + (\text{time_taken_new} / \text{faster times})$

Here, faster times is 2 (given)

Time is 1.

a)

Time taken new for floating point is $1 * 20 / 100 = 0.2$

$$\text{Speedup} = 1 / (1 - 0.2) + (0.2/2)$$

$$= 1 / (0.8) + 0.1$$

= **1.11 i.e., 11 % overall speedup for fast floating-point operation**

b)

The Speedup would include the cache time of 10% time consumed and $\frac{2}{3}$ speedup in addition to floating point.

Time taken new for data cache is $1 * 20 / 100 = 0.2$

$$\text{Speedup} = 1 / [(1 - 0.2 - 0.1) + (0.2/2) + (0.1 * 3/2)]$$

$$= 1 / [(0.7) + (0.1) + (0.15)]$$

= $1 / 0.95 = \mathbf{1.05 \text{ i.e., } 5\% \text{ overall speedup}}$

c)

Formula utilized: $\text{Run time for each} = (\text{TT_new} / \text{faster times}) / (1 - \text{TT_new}) + (\text{TT_new} / \text{faster times})$

$$\text{Run time for floating point} = (0.2/2) / [(1 - 0.2 - 0.1) + (0.2/2) + (0.1 * 3/2)]$$

$$= 0.1 / 0.95$$

= **0.105 i.e., 10.5% of time**

$$\text{Run time for data cache access} = (0.1 * 3/2) / [(1 - 0.2 - 0.1) + (0.2/2) + (0.1 * 3/2)]$$

$$= 0.15 / 0.95$$

= **0.157 i.e., 15.7% of time**

Answer to Question 8 is the same as Question 7.

Answer 8)

Formula utilized: $\text{Net Speedup} = 1 / (1 - \text{time_taken_new}) + (\text{time_taken_new} / \text{faster times})$

Here, faster times is 2 (given)

Time is 1.

a)

Time taken new for floating point is $1 * 20 / 100 = 0.2$

$\text{Speedup} = 1 / (1 - 0.2) + (0.2 / 2)$

$$= 1 / (0.8) + 0.1$$

= 1.11 i.e., 11 % overall speedup for fast floating-point operation

b)

The Speedup would include the cache time of 10% time consumed and $\frac{2}{3}$ speedup in addition to floating point.

Time taken new for data cache is $1 * 20 / 100 = 0.2$

$\text{Speedup} = 1 / [(1 - 0.2 - 0.1) + (0.2 / 2) + (0.1 * 3 / 2)]$

$$= 1 / [(0.7) + (0.1) + (0.15)]$$

= 1 / 0.95 = 1.05 i.e., 5% overall speedup

c)

Formula utilized: $\text{Run time for each} = (\text{TT_new} / \text{faster times}) / (1 - \text{TT_new}) + (\text{TT_new} / \text{faster times})$

Run time for floating point = $(0.2 / 2) / [(1 - 0.2 - 0.1) + (0.2 / 2) + (0.1 * 3 / 2)]$

$$= 0.1 / 0.95$$

= 0.105 i.e., 10.5% of time

Run time for data cache access = $(0.1 * 3 / 2) / [(1 - 0.2 - 0.1) + (0.2 / 2) + (0.1 * 3 / 2)]$

$$= 0.15 / 0.95$$

= 0.157 i.e., 15.7% of time
